NO.40 つらい経験について書くことの効用(2)

In an experiment that followed, another group of healthy students were given the four-day writing exercise. Some chose to write about highly personal and upsetting experiences (including loneliness, problems with family and friends, and death). When questioned immediately afterwards, they stated that they did not feel any better. However, their blood samples taken before and after the experiment showed evidence of an improved resistance to illness. The white cells that fight off bacteria and viruses had increased their reaction and sensitivity to these "invaders." This trend continued over the following six weeks, when another blood sample was taken. Individuals who showed the best results were those who wrote about topics that they had actively refrained from telling others about.

The researchers propose that failure to face up to painful experience can be a form of stress itself, and can increase the possibility of illness. It follows, then, that actively dealing with a major shock makes possible its understanding and acceptance. The answer is not to suffer in silence. It may not always be possible to talk about personal problems, but writing them down will help the body to fight disease in the long run.
